Sample Questions and Answer Key Details

1. What is natural selection, and how does it lead to evolution?

Answer:

Natural selection is the process whereby organisms with advantageous traits are more likely to survive and reproduce, passing those traits to their offspring. Over time, this process causes the frequency of beneficial traits to increase in a population, leading to evolution. Specifically, natural selection depends on variation within populations, differential survival and reproduction, and heredity.

2. Describe three types of evidence that support the theory of evolution.

Answer:

- Fossil Record: Provides chronological evidence of past life forms and transitional species.
- Comparative Anatomy: Shows structural similarities (homologous structures) among different species, indicating common ancestry.
- Molecular Biology: DNA and protein comparisons reveal genetic relationships and evolutionary distances.

3. Explain the concept of homologous structures and give an example.

Answer:

Homologous structures are body parts that are similar in structure but may serve different functions in various species, indicating a common evolutionary origin. An example is the forelimbs of humans, whales, and bats, which have similar bone arrangements despite differing functions.

4. What is genetic drift, and how does it differ from natural selection?

Answer:

Genetic drift is a random change in allele frequencies within a population, often occurring in small populations, regardless of whether the traits are advantageous. Unlike natural selection, which is driven by environmental pressures favoring certain traits, genetic drift is a stochastic process that can lead to significant genetic changes purely by chance.

5. Define speciation and describe one mechanism by which it occurs.

Answer:

Speciation is the evolutionary process by which populations evolve to become distinct species. One

mechanism is allopatric speciation, which occurs when populations are geographically separated by barriers like mountains or rivers, preventing gene flow and leading to divergence over time.

Detailed Explanation of Key Concepts

Mechanisms of Evolution

Understanding how evolution occurs involves examining several mechanisms:

- Natural Selection: The primary driver of adaptive evolution.
- Gene Flow: Movement of alleles between populations, which can introduce new genetic variation.
- Genetic Drift: Random fluctuations in allele frequencies.
- Mutation: Introduction of new genetic variations, which can be acted upon by other mechanisms.

Patterns of Evolution

Evolutionary patterns illustrate how species change over time:

- Divergent Evolution: When related species become more different.
- Convergent Evolution: When unrelated species develop similar traits due to similar environments.
- Coevolution: When two species influence each other's evolution, such as predators and prey.

Speciation and Its Types

Speciation can occur through different processes:

- Allopatric Speciation: Geographic isolation leads to divergence.
- Sympatric Speciation: Species diverge within the same geographic area, often due to reproductive barriers.
- Parapatric and Peripatric Speciation: Less common but also important mechanisms.

Alleles are different versions of a gene. An individual inherits one allele from each parent. The combination of alleles determines the organism's traits.

Dominant and Recessive Traits

Traits are expressed based on the dominance relationships between alleles:

- **Dominant allele:** masks the effect of the other allele and is expressed in the phenotype.
- **Recessive allele:** only expressed when two copies are present.

Patterns of Heredity

Mendelian Genetics

Gregor Mendel's experiments with pea plants established the fundamental laws of inheritance:

- **Law of Segregation:** each parent passes one allele for a trait to their offspring.
- **Law of Independent Assortment:** genes for different traits are inherited independently of each other.

Punnett Squares and Predicting Offspring

A Punnett square is a tool used to predict the probability of offspring inheriting particular traits based on parental genotypes. It helps visualize how alleles combine during reproduction.

Genotype and Phenotype

- **Genotype:** the genetic makeup of an organism (e.g., AA, Aa, aa).
- **Phenotype:** the observable traits resulting from the genotype (e.g., purple flowers, tall height).

Mendelian Genetics

Sample Question:

In pea plants, tall (T) is dominant over short (t). If two heterozygous plants are crossed, what is the probability their offspring will be short?

Answer Explanation:

Using a Punnett square, crossing Tt x Tt yields:

| T | t |

|---|---|

| T | TT | Tt |

| t | Tt | tt |

Genotypic ratios: 1 TT : 2 Tt : 1 tt

Phenotypic ratios: 3 tall : 1 short

Probability of short offspring (tt): 1/4 or 25%.

Genetic Crosses and Probability

Sample Question:

What is the chance of obtaining a heterozygous offspring when crossing a homozygous dominant individual with a heterozygous one?

Answer Explanation:

Crossing AA x Aa:

| | A | A |

|---|---|---|

| A | AA | AA |

| a | Aa | Aa |

Results: 2 Aa (heterozygous) out of 4 total, so 50% chance.
